## Office Memorandum • United States Government

Inclosure contains seds-word matter)

One of the contains of t

DATE: 13 June 1952

FROM:

Dago,

SUBJECT:

Willigation of Analytical Machinery.

In after you told me to study this subject, I found that, before I could really start, I had first to determine what the problems are, and that before I spald start to de that I had to find out what machinery we have and what it does. This sounded say, but a search revealed that we had no entalogue of this information. I have therefore had to make my own. Here is a copy of it. Although it has been carefully shocked and rechecked with the technicians involved, it is unspectedly subject to revision and improvement on many counts, and it is hoped that the responsible operators will soon sollaborate on an authentic, properly staffed-sat satelogue; menualle you may find it useful to retain this first tentative affect for reference until a better one comes along. All other interested parties have copies.

2. Downgraded to CONFIDENTIAL on removal of the inclosure.

R. S. L. GOODWIN Captain, U.S. Nevy

#### Machines Used in Cryptanalysis

- I. There has not been available a listing of cryptomalytical machines which puts them in their logical relationship to one another and in their proper perspective from the relatively "lay" standpoint of the users, or of management authorities broadly interested in the application of machinery to cryptomalysis as a whole. The AFSA Technical Committee's paper "T/CA2" attempts a categorisation, but its arrangement appears to be from the standpoint of the development engineers, with only indirect reference to purposes and results. This listing is an attempt to fill the gap and, at the sums time, to present speed and performance data in terms of practical accomplishment, rather than interest of the various internal and contributory processes which have too often in the past been cited in statements of the machines' expebilities.
- 2. The machines have been listed under three anjer estegation by applicability; i.e., "broad", "narrow", and "specific". These applicability octogories as used here are of course only relative, with arbitrary division lines and some everlaps and anomalies. Within these major estegation, the machines are listed by approper under two heads; vin, "smallysis" (having as primary purpose the tailying and presentation of statistics for smallysis) and "colution" (having as primary purpose the "solving" (at least testative and partial) of individual messages). Here, too, there is an arbitrary lime, and some enomaly. Within the two purpose estegation, in turn, the sub-listing is according to function, as described in the next paragraph.
- 3. Because the functional entegories "comparator" and "computer" hitherto used are constinue considerably overlapping and have therefore led to some confusion, three new function entegories have been adopted for this listing; i.e., counters, selectors, and operators, representing three degrees of capability on an accounting scale in that under. All three "lock" at everything fud into them; the counter counts everything it looks at, the selector is capable of choosing parts of what it looks at and counting or indicating only them, the operator is capable of putting parts or all of what it looks at through certain processes other than or in addition to counting. It would seem that each of the two higher classes would enhant the essentials of the classes below it, and this is, in general, the case; operators can be used as counters, but not necessarily efficiently (in this connection, see the notes appended to IRM, ATLAS, ARDUR, ROMAD, GUIDERS, ARD CORNER; notes 4 to 8, inc., and note 15). As for the relationships of the new function categories to the old, about all that can be said in that everything that has been or might validly be salled a "computer" in an epsyster, but the reverse is not necessarily true.
- 4. At the end of the listing is a category of machines used in properation which might be listed under that as a function but which, because the machines solely serve and are used in conjunction with other machines, particle of the applicability and purposes of their can. These are listed solely because they impose, on the other machines, various speed and time limitations which must always be kept in mind as the "speed" entries for the state machines are used in estimates of especity and evailability.
- 5. Malague machines whose purpose is simply decryption or "hand testing" or the generation of specific key for other machines (sither experiency or as applique units) are not separately listed hereis (Sete 1; see page 25). In addition, machines which, although having individual names, are essentially appurtenances of the conventional IBM complex (such as MISTRESS) or which are peripheral to other machines (such as BEAR) are not listed.

Brack/AFSA Impertur/13 June 1952

# Hachines Used in Cryptonelysis (costigued)

Broad applicability - Applicable is cryptenalytic attack against any cryptegraphic system, or systems of more than one broad category. Nexton applicability - Applicable is cryptenalytic attack against only one category of cryptegraphic systems or only a few systems. secific applicability - Applicable in crypteralytic attack against only one specific ersten. The categories and subcategories described above (misss "properation") are briefly defined and related below for convenience.

Purpose "similysis" - Baring as its purpose the tallying of statistics or the finding of phanomena and symptoms to be used in

cryptanalyads.

Purpose "solution" - Eaving as its purpose the salution of individual nessenges or parts of them; that is, their rendering into at least partial intelligible tent, or into at least partial encrypted text requiring a distinct further or different salution edminae.

Function, counting - Tallying complete statistics of its bind on the data fed to it.

Function, selecting - Tallying or indicating white statistics; that is, selecting, counting, or indicating irregularly occurring events in the data fed to it.

"smalysis" function, that the "solvers" are crowded toward the "specific" and of the applicability scale, that several categories (nore, in fact, then otherwise) are completely blank. The fact that this is merely a bias rather than a rigid or necessary correlation is the principal reason why the older and simpler categoriesticss (which are partly based on approximate groupings in terms of surrent neason rather than legic) have sometimes been confusing and mislanding to persons other than those who are intimate with the field. A third dimension is messed, and has here Function, operating - Perfering combining operations with the data fed to it.
It will be noted that the distribution of subcategories in the listing is markedly biased; for example, that the "counters" are confined to the

- 7. In addition to the anguelies and everlaps within each schelon of categories, there are ancaelies and everlaps between schelons, brought about by the exigencies of chelon where choice exists. For example, COLUMNIE, listed under their whighest expability as analysis spareform, and as such of parrow applicability, have, if regarded as analysis selectors (which they also are), broad applicability.
- of any thirty-six binds of things taken two at a time, and that "textes" and "digraphit, frequency exacts" muraly happens to be a typical expression of this ability in its usual orgitanalytical applications; many other expressionalytic applications of this sensiting capability sus 8. The descriptive matter in the listing has to strike a mean between, on the one hand, the destrability of completely objective attribution in broadest possible terms and, on the other hand, the necessity of keeping the data reasonably foun to earth and in terms of the keeps or now usual cryptemalytic applications. For this reason it must be kept in mind throughout that, in most eases, the given impute and functions are ecomplary rather than limiting. Thus (to plok the first item in the list), although ALCAUNIZ is stated to receive "texto" and to make "Migraphic and columnar frequency sounds", it must be remembered that what it actually done is to make counts of the occurrences

The state of the s

#### Kotes

- Note 1 Under this limitation the following are emitted from the list: OPRIS, MAISIS, N-8, SATTR (and other Magelia analogue devices), N-211, STURMENT, and AFEAF-13.
- Note 2 The most costly machine in the list.
- Here 3 Definitions. Sliding Howing two streams of data relative to each other to permit their being operated on or compared at every possible desired alignment of one with the other.

  Sorting Hearranging the order in which the data of a stream of data are evailable for use.

  Collating Shaffling two streams of data into one in a desired order. As a special case, shaffling a small body of new data into one already ordered stream of old data.
- Note 4 There are various devices having separate names (such as HISTHESS) which are commutably appartenances of the conventional complex rethereties independent mechanics, and which are therefore act listed separately. In addition to its usefulness as an operator, HEM is catstandingly usuful as a counter of polygraphs of trigraph and higher and as a selector of relatively frequent occurrences. Useful for
  "solution" as well as "emplysis". Particularly applicable where long and complex listings and arrangements of written data are wested
  in connection with the needs of analysis.
- Bute 5 As new compared, NCMAD will be compareble to the entire INM complex with a speed advantage ever INM of the order of 100 to one, but without the flexibility in employment afforded by the discontinuity of INM processes and the safety inherent in INM's committed multiplicity, replacembility, and dispursion.
- Hote 6 Oxtotandingly neeful as selectors, and limited in use as such only by the domands on them for use as operators. Framept for COLIMENO and COMMIR, have wide applicability to "solution" as well as "anniputs".
- Note 7 ATLAS II is essentially a more capacitous ATLAS I with provision for keeping the active data more available, so that ready aliding ability is added. This emables it to do all that ATLAS I sum do more readily, and in addition to add to the processes the aliding feature.
- Note 8 ATLAS I and ABNTE are unumreased among machines now available in operations with multiple depths of data (with ATLAS I, for lack of sliding ability, alignment in depth should be supplied) where weighting is involved, and where there are complex interrelationships involving choice in the course of and as part of the untomatic operation. The "Roststrap" specialism is a netowarthy case in point.
- yebs 9 The IBM 604, the dear calculators, O'MALIEY, and MCRECID may be regarded as constituting a special entegery by function, that of "calculators". As distinguished from all of the other machines listed, which receive and perform various functions with text and her, they are purely subhemblook; weathing, using, and producing making but subhemblook information.

the series

#### Notes (continued)

- Note 10 Those narrow solution operators are all of "marrow" applicability only in that they are applicable solicity end not to wired-sheel systems. Idditive systems constitute a bread class of cryptography, and these operators are applicable to a large number and variety of individual systems within that class. The term "marrow" is thus used relatively merely to distinguish these mechanisms from those which can be used against both wired-sheel and additive systems.
- Note 11 For message placement in a key-streem, AMSER is applicable to all problems, including these where there is no phase or "best" in the placement (as with underlying plain text which can start at any key position), while SEATE II and SIED are particularly applicable to problems where there is place or best (as with underlying code groups, particularly where there are likely to be level starts of smessages at known intervals in the key streem). It will be noted, too, that, for a "Round Rebin" with short messages, AMSER is of the order of 25 times as fast as a single ROBIN, and thus night have the edge on the entire 15 machine ROBIN bettery; but it must not be forgotten in this connection that there is film proparation time to consider in addition, and that AMSER, unlike ROBIN, movely lacentee high coincidences, without giving the statistics on them, and in, by the nature of its operation, not particularly unefal for locating more than the few very highest.
- Note 12 Unoful as an "analysis" operator also, and in this employment is comparable to COLDERG.
- Note 13 There are a number of others in storage.
- Note 14 The conditions expressed under "Function" practically limit HTPO to use on Enigen and Enigen—like systems. It is functionally expelle of such broader application, but as the Enigma principle is departed from MTPO rapidly yields superiority to AMER and even to some of the analytical selectors, so that its broader capability is not practically useful, and, doubte an inherent verentility which the other specific solution selectors cannot match, has to be listed soung them.
- Hate 15 Because of the wide variety of their applications, statements of the speed capabilities of these analytic operators are assessarily specific and multiple, and all simplifications are likely to be artificial, signs operations within the capabilities of other machines would hardly be assigned to these, and operations particularly suited to the capabilities of these would usually be impossible for the others. Thus, although this expensive equipment can extraction make the decrease of the sensible or communical to use it for MEGATF's and AIGATRAZ, it would not be sensible or communical to use it for MEGATF's and AIGATRAZ's work, or to waste time devising ways in which this could be done, as long as the two chapper and less versable equipments are there to do it. NCMAD's performance is shown in terms of two data-corting operations only, because serting of large assesses of data will be MAMAD's extending may contribution to the capabilities of the "computers"; actually, in addition, NCMAD will probably be at least comparable to ATLAS II and ATMER for all of the other convetions listed. (Maniables on most wast.)
